

Instructor Notes and Answer Key

Part I

1. The expression below shows the units of four quantities multiplied together. Determine the units of the resulting quantity.

$$\frac{\text{meters}}{\text{seconds}} * \frac{\text{miles}}{\text{meters}} * \frac{\text{seconds}}{\text{minutes}} * \frac{\text{minutes}}{\text{hours}} = \frac{\text{miles}}{\text{hour}}$$

2. The equation below shows only the units of each quantity involved. Determine the units for the missing quantity.

We need the tons in the first fraction and the pounds in the third fraction to cancel out.

$$\text{a. } \frac{\text{acres}}{\text{tons}} * \frac{\text{tons}}{\text{pounds}} * \frac{\text{pounds}}{\text{person*day}} * \frac{\text{days}}{\text{year}} = \frac{\text{acres}}{\text{person*year}}$$

- b. How would you write or say the unit $\frac{\text{acres}}{\text{person*year}}$ in words?

Acres per person per year

3. We have choices when buying light bulbs. A 60 Watt incandescent bulb, a 13 Watt compact fluorescent bulb (CFL), and a 3 Watt light-emitting diode (LED) all produce the same amount of light. Refer to the graph on the previous page to determine the CO₂ emitted by three people in Iowa, who each burn a different type of bulb 8 hours a day, every day, for a year. Give your answers in cubic feet.

- a. CO₂ emissions for the incandescent bulb:

$$8 \text{ hours} * 365 \text{ days} = 2920 \text{ hours}$$

$$\frac{60 \text{ W} * 2920 \text{ hrs}}{\text{year}} * \frac{1 \text{ MW}}{1,000,000 \text{ W}} * \frac{1222 \text{ lbs}}{1 \text{ MWh}} * \frac{8.57 \text{ ft}^3}{1 \text{ lb}} = 1834.79 \text{ ft}^3 \text{ of CO}_2 \text{ per year}$$

- b. CO₂ emissions for CFL bulb:

$$\frac{13 \text{ W} * 2920 \text{ hrs}}{\text{year}} * \frac{1 \text{ MW}}{1,000,000 \text{ W}} * \frac{1222 \text{ lbs}}{1 \text{ MWh}} * \frac{8.57 \text{ ft}^3}{1 \text{ lb}} = 397 \text{ ft}^3 \text{ of CO}_2 \text{ per year}$$

- c. Can you predict the CO₂ emissions for the LED without redoing the whole calculation? What is the CO₂ emissions for the LED?

The only difference between the previous two calculations is that the 60W changed to 13W,

so this can be solved easily by setting up a proportion: $\frac{60 \text{ W}}{1834.79 \text{ ft}^3} = \frac{3 \text{ W}}{91.74 \text{ ft}^3}$

4. Now suppose that everyone in the United States operates an identical lamp such as in question 3 for 8 hours a day, every day, for a year. Use the graph to identify the average CO₂ emissions from electricity production in the United States and calculate the total carbon emissions for each type of bulb. Write your answers in scientific notation.

- a. Total CO₂ emissions if everyone used incandescent bulbs:

$$\frac{60 W * 2920 hrs}{year} * \frac{1 MW}{1,000,000 W} * \frac{1041 lbs}{1 MW} * \frac{8.57 ft^3}{1 lb} * \frac{325,700,000}{1} = \mathbf{5.09 \times 10^{11} ft^3}$$

- b. Total CO₂ emissions if everyone used LEDs:

$$\frac{60 W}{5.09 \times 10^{11} ft^3} = \frac{3 W}{\mathbf{2.55 \times 10^{10} ft^3}}$$

5. Use your answer from problem 4a to determine how many Superdomes this CO₂ would fill. The volume of the Superdome is 155 million cubic feet.

$$\frac{5.09 \times 10^{11} ft^3}{155 \times 10^6 ft^3} = \mathbf{3,283.87 \text{ superdomes}}$$

6. Which number is easier for you to understand and relate to, the answer from 4a in cubic feet, or the answer from 5 in terms of Superdomes? Write a few sentences explaining which you chose and why.

For most of us, it is easier to imagine how big a few thousand stadiums would be than to make sense of trillions of cubic feet. Even so, 3283 superdomes is still enormous. For further exploration you could compare the area they would cover to the size of various locations such as cities or islands. How does this compare to the size of Manhattan?

Part II

7. In 2016 the total carbon footprint of the United States was 5.7×10^9 tons of CO_2 . Look up the US population for 2016. What was the average American's carbon footprint that year?

The US population in 2016 was 323.4×10^6 people. $\frac{5.7 \times 10^9 \text{ tons}}{323.4 \times 10^6 \text{ people}} = \mathbf{17.63 \text{ tons per person}}$

8. Forests absorb CO_2 from the air, and different types of forests absorb different amounts. But on average, an acre of forest can absorb 4.9 tons of carbon in a year. How many acres of forest are needed to absorb one average American's carbon emissions?

$$\frac{17.63 \text{ tons}}{\text{person}} * \frac{1 \text{ acre}}{4.9 \text{ tons}} = \mathbf{3.60 \text{ acres per person}}$$

9. How many acres of forest are needed to absorb all of the CO_2 that the United States produces?

$$\frac{3.6 \text{ acres}}{\text{person}} * 323.4 \times 10^6 \text{ people} = \mathbf{1.16 \times 10^9 \text{ acres}}$$

10. Look up the amount of forest in the United States. Before European colonization of North America this same region had 1.023×10^9 acres of forest. What is the percentage change in the amount of forest since colonization?

There are currently 747 million acres of forest, whereas in the past there were 1023 million acres.

$$\frac{747 - 1023}{1023} = \mathbf{-26.98\%}$$

11. Do we have enough forest in the United States to absorb all of the CO_2 that we produce? If we still had all the forests that we had before Europeans arrived, would we have enough? What do you think happens with the excess – either the excess carbon or the excess forest? Write a paragraph to answer these questions and to explain what you think happens and why.

We do not have enough forest to absorb all of our carbon emissions. If we still had all of the original forests we would come much closer to having enough, but still not quite be there. All of our extra CO_2 remains in the atmosphere and moves over other countries – can their forests absorb our excess? Unfortunately, no. While we have higher emissions per capita than other countries, we also have a much higher than average portion of our land forested. We don't have enough forests to absorb it all, and other countries don't, either.

Part III

12. Americans love pizza! According to *Packaged Facts* we each eat, on average, 46 slices per year, and much of that is delivery or takeout. If you took all of the cardboard pizza boxes used in the United States over one year and stacked them one on top of the other, about how many miles do you think this stack would reach? Take a guess.

There are no wrong answers to this problem.

13. In order to calculate the height of the stack, what assumptions will you need to make, and what information will you need to know?

Various answers could be correct, depending on your approach.

The number of pizza boxes used in a year

The number of slices in the average pizza

What proportion of pizzas are transported in takeout boxes

The height of an average pizza box in inches

Conversions from inches to miles

14. Look up the items in your list from question 13 and calculate the actual height of the stack.

According to webrestaurantstore.com pizza boxes are 1.75" high. Assuming that 75% of pizzas are transported in a box, and that the average pizza has eight slices, we have:

$$\frac{1 \text{ pizza}}{8 \text{ slices}} * \frac{46 \text{ slices}}{\text{person}} * 325.7 \times 10^6 \text{ people} = 1.87 \times 10^9 \text{ total pizzas eaten}$$

$$.75 * 1.87 \times 10^9 = 1.4 \times 10^9 \text{ pizza boxes used}$$

$$\frac{1.75 \text{ inches}}{\text{box}} * \frac{1.4 \times 10^9 \text{ boxes}}{1} * \frac{1 \text{ foot}}{12 \text{ inches}} * \frac{1 \text{ mile}}{5280 \text{ feet}} = 38,668 \text{ miles}$$

15. Mount Everest is 5.5 miles high. How many times higher is the stack of pizza boxes that go to American landfills every year?

$$\frac{38,668 \text{ miles}}{5.5 \text{ miles}} = 7,010.5 \text{ times as high.}$$

16. Write a couple of sentences to describe how your guess relates to the actual height of the stack.

Most of us will significantly underestimate this. 38,668 miles is almost 1/6 of the distance to the moon!
